Abstract: (joint work with Mariano Mateos)

In this talk, we derive a priori error estimates for the finite element discretization of Dirichlet control problems with pointwise state constraints. The problem class is particularly challenging due to the low regularity of the states with L^2 -Dirichlet boundary controls. To obtain an optimality system of Karush-Kuhn-Tucker type with Lagrange multipliers for the pointwise state constraints prescribed in the interior of a 2D polygonal domain, we make use of higher interior regularity results for harmonic functions. Based on these results, finite element error estimates are derived with techniques that separate the regularity-limiting influences of the corners of the domain on the one hand, and the support of the Lagrange multiplier in the interior of the domain on the other hand. currently under investigation.
